Title: Commercial Production of Chymosin in Plants

5 *Sub*
2.1 This application is a continuation-in-part application of United States serial no. 09/378,696, filed on August 23, 1999, which is incorporated herein by reference in its entirety.

FIELD OF THE INVENTION

The present invention relates to improved methods for the recombinant production and isolation of chymosin from plants.

BACKGROUND OF THE INVENTION

10 Chymosin, also known as rennin, is a commercially important enzymatic protein, commonly used in the cheese manufacturing industry to coagulate milk. Traditionally chymosin has been prepared from its natural source, the fourth stomach of unweaned calves, although recovery from the stomachs of other mammals, such as lamb, goats etc. heretofore
15 was known. More recently, primarily as a result of a decrease in calf production, recombinant DNA techniques have been employed to produce chymosin by fermentation in genetically engineered microorganisms. Thus a variety of bacterial and fungal hosts have been genetically modified to produce chymosin by fermentation, including for example, the bacterial
20 hosts *Escherichia coli*, (European Patent 0 134 662 A1; Nishimori *et al.* (1982) J. Biochem 91: 1085-1088.), *Bacillus subtilis* (US patent 5,624,819; 5,716,807 and Parente *et al.* (1991) FEMS 77: 243-250) and the fungal hosts *Aspergillus* sp. (European Patent 0 575 462 B1; US patents 5,364,770 and 5,863,759; Cullen *et al.* (1987) Bio/Technology 5: 369-375., Dunn-Coleman *et al.* (1991) Bio/Technology 9: 976-981., and Tsuchiua *et al.* (1993) Appl. Microbial Biotech. 40: 327-332), *Kluyveromyces lactis* (van der Berg *et al.* (1990) Bio/Technology 8: 135-139 and *Trichoderma ressei* (Jarkki *et al.* (1989) Bio/Technology 7: 596-603; Pitts *et al.* (1991) Biochemical Society Transactions 19: 663-665). As well, more general expression in fungi, yeast
25 and bacteria (US Patents 4,666,847) and in filamentous fungi (US patent 5,578,463).

The active enzyme chymosin (E.C. 3.4.23.4) is comprised of a polypeptide chain of a molecular mass of 35.6 kDa. However crude extracts of calf stomach mucosa in addition to active chymosin, contain two inactive precursor polypeptides known as pre-pro-chymosin and pro-chymosin. Pre-pro-chymosin contains an extra 58 amino acids at the N-terminus, whereas pro-chymosin contains an extra 42 amino acids. Conversion of the inactive precursor protein into enzymatically active chymosin requires the step-wise removal of the chymosin pre-peptide and pro-peptide. *In vivo* these activation steps take place in the calf stomach. The chymosin pre-peptide directs secretion of the polypeptide by the stomach cells and is removed upon secretion of the polypeptide by the stomach cells. The chymosin pro-peptide is subsequently removed in the gastric lumen, thereby activating the enzyme. The activation reaction can also be performed *in vitro* at pH values below 5. With regards to the enzyme chymosin, it should further be noted that chymosin purified from calf stomach is a mixture of two different polypeptides known as chymosin A and chymosin B. Both of these polypeptides are active and differ only with respect to one amino acid. The amino acid residue at position #290 is an aspartate residue in chymosin A and a glycine residue in chymosin B (Foltman *et al.*, (1977) Proc. Natl. Acad. Sci. USA 74: 2331-2324; Foltman *et al.*, (1979) J. Biol. Chem. 254: 8447-8456).

There are several disadvantages associated with the recombinant production of chymosin in fermentation systems. In general, fermentation systems require the use of large fermentation vessels that have both large space and energy requirements and consequently are costly. As well, the growth media require large volumes of water and may require special chemicals. Both of these may present environmental issues in the disposal of the large amounts of potentially harmful waste. Further, storage and shipment of raw material containing chymosin is problematic. The bacterial or fungal fermentation broth need to be processed immediately or refrigerated in large volumes since the enzyme is not stable for long periods in the broth.

The use of plants as bioreactors for the commercial production of recombinant proteins is well known. For example, avidin, β -glucuronidase and aprotinin (see patents US Patents 5,767,379, 5,804,694 and 5,824,870) have been recombinantly expressed in corn. Further, US
5 Patents 5,543,576 and 5,714,474 are broadly directed to the recombinant production of enzymes in seeds and to the use of seeds or milled seeds comprising enzymes as a raw material in the preparation of food and feed products. Although US Patents 5,543,576 and 5,714,474 suggest chymosin as one potential enzyme that may be produced in seeds, there is no
10 reduction to practice. These patents are further limited by the fact that in order to use the chymosin for the commercial production of cheese, chymosin would have to be purified from the seed or milled seeds.

PCT patent application WO 92/01042 discloses the expression of chymosin in the leaves of transgenic tobacco and potato plants. According
15 to the disclosure chymosin expression levels of only 0.1% to 0.5% (w/w) of total soluble leaf protein were attained. The methodology of WO 92/01042 is further limited in that the production in leaves would require immediate extraction of the enzyme from the leaf material upon harvesting of the plants as the enzyme would lose activity when stored in
20 leaves. In addition, due to the relatively high water content of leaves, large amounts of biomass must be processed.

There is a need in the art to further improve methods for the recombinant expression of chymosin in plants.

SUMMARY OF THE INVENTION

25 The present invention relates to novel and improved methods of producing commercial levels of chymosin in transgenic plants. The inventors have found that chymosin when expressed in the seeds of transgenic plants accumulates to levels of at least 0.5% (w/w) of total seed protein.

30 Accordingly, the invention provides a method for the production of chymosin in a plant seed comprising:

a) introducing into a plant cell a chimeric nucleic acid sequence molecule comprising in the 5' to 3' direction of transcription:

- 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
- 5 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
- 3) a third nucleic acid sequence capable of terminating transcription in said plant cell;

b) growing said plant cell into a mature plant capable of
10 setting seed; and

c) obtaining seed from the mature plant wherein said seed contains chymosin.

Preferably, at least 0.5% (w/w) of the total seed protein is chymosin.

15 The present invention also provides a method for the production of plant seeds containing at least 0.5% (w/w) chymosin in the total seed protein comprising:

(a) introducing into each of at least two plant cells a chimeric nucleic acid sequence molecule comprising in the 5' to 3' direction of
20 transcription:

- 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
- 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
- 25 3) a third nucleic acid sequence capable of terminating transcription in said plant cell;

(b) growing each plant cell into a mature plant capable of setting seed;

(c) obtaining seed from each mature plant;

30 (d) detecting the levels of chymosin in the seed of each plant obtained in step (c) or in the seed of a plant generated from the seed of a plant obtained in step (c); and

(e) selecting plants that contain at least 0.5% (w/w) chymosin in the total seed protein.

In preferred methods of the present invention, the nucleic acid sequence capable of regulating transcription is a seed-specific promoter. In further preferred methods, the chimeric nucleic acid sequence additionally comprises a signal sequence capable of targeting the chymosin polypeptide to the plant apoplast. In further preferred methods, the nucleic acid sequence encoding chymosin sequence is optimized for plant codon usage and the chymosin sequence further contains the chymosin pro-peptide or pre-pro-peptide or pre-peptide sequences.

In a further aspect, the present invention provides plant seeds expressing chymosin. In a preferred embodiment of the present invention, the plant seeds comprise a chimeric nucleic acid sequence comprising in the 5' to 3' direction of transcription:

- 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
- 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
- 3) a third nucleic acid sequence capable of terminating transcription in said plant cell wherein the seed contains chymosin.

Preferably, at least 0.5% (w/w) of the total seed protein is chymosin.

In another aspect the present invention provides plants capable of setting seed expressing chymosin. In a preferred embodiment of the invention, the plants capable of setting seed comprise a chimeric nucleic acid sequence comprising in the 5' to 3' direction of transcription:

- 1) a first nucleic acid sequence capable of regulating transcription in a plant cell operatively linked to;
- 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;

- 3) a third nucleic acid sequence capable of terminating transcription in said plant cell, wherein the seed contains chymosin.

In yet another aspect the present invention provides a method for recovering chymosin from plant seeds. Accordingly, the present invention provides a method for obtaining chymosin from a plant seed comprising:

- a) introducing into a plant cell a chimeric nucleic acid sequence molecule comprising in the 5' to 3' direction of transcription:
 - 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
 - 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
 - 3) a third nucleic acid sequence capable of terminating transcription in said plant cell;
- b) growing said plant cell into a mature plant capable of setting seed;
- c) obtaining seed from the mature plant wherein said seed contains chymosin; and
- d) isolating said chymosin from said seed.

In preferred embodiments, isolation of chymosin from seed in step (d) comprises:

- (i) crushing of the plant seed to obtain crushed plant seed;
- (ii) contacting the crushed plant seed or a fraction thereof with a protein binding resin; and
- (iii) recovering the chymosin from the protein binding resin.

In further preferred embodiments upon crushing of the plant seed the crushed seed material is fractionated into (a) an aqueous phase containing substantially all of the chymosin, (b) an oil fraction, and (c) a fraction containing the insoluble material insoluble material. Accordingly step (d) more preferably comprises:

- (i) crushing of the plant seed to obtain crushed plant seed;

- (ii) fractionating the crushed plant seed into an oil fraction, aqueous fraction and a fraction comprising insoluble material;
- (iii) contacting the aqueous fraction with a protein binding resin; and
- (iv) recovering the chymosin from the protein binding resin.

In a preferred embodiment, the protein binding resin is a hydrophobic interaction resin. In further preferred embodiments of the invention, the isolation of the chymosin further comprises the employment of an ion exchange resin and a hydrophobic interaction resin.

Other features and advantages of the present invention will become readily apparent from the following detailed description. It should be understood, however, that the detailed description and the specific examples while indicating preferred embodiments of the invention are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art of this detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

The invention will now be described in relation to the drawings in which:

Figure 1 shows the nucleotide sequence (SEQ.ID.NO.:1) and corresponding amino acid sequence (SEQ.ID.NO.:2) of the open reading frame of a pre-pro-chymosin sequence. The "pre" sequence is indicated in *Italics* between and including amino acids 1 to 26. The "pre" sequence encodes a signal sequence identical to the PR-S signal sequence from tobacco sequence (Sijmons *et al.* (1990) Bio/technology 8: 217-221). Amino acids 27 to 67 inclusive are the "pro" sequence with the remaining amino acids encoding the mature chymosin polypeptide.

Figure 2 shows the nucleotide sequence (SEQ.ID.NO.:3) of the phaseolin promoter- a pre-pro-chymosin-phaseolin terminator sequence responsible for the high levels of expression of chymosin in plant seeds.

Figure 3 is a Western blot analysis comparing a chymosin standard and a protein extract of seeds from a *Brassica* plant expressing chymosin.

Figure 4 is a bar diagram showing the expression of chymosin
5 in flax seeds derived from independent transformed flax plants.

Figure 5 shows a SDS-polyacrylamide gel showing progressive purification of chymosin obtained from transgenic seeds of *Brassica napus* as described in example 5.

DETAILED DESCRIPTION OF THE INVENTION

10 As hereinbefore mentioned, the present invention relates to improved methods for the production of chymosin in transgenic plants. The present inventors have surprisingly found that by expressing chymosin in the seeds of plants, chymosin accumulation levels exceeding 0.5% (w/w) of total seed protein may be attained. These high expression
15 levels in plant seeds allow significant commercial savings since the acreage of plants that needs to be grown can be limited and the amount of biomass that must to be subjected to extraction is reduced. The amount of biomass processed is further limited due to the relatively low water content present in plant seed. Furthermore, the expression in plants seed
20 offers flexibility in storage and shipment of chymosin as a raw material, since chymosin retains its enzymatic activity upon extraction from stored seed.

Accordingly, the invention provides a method for producing chymosin in plant seeds comprising:

25 a) introducing into a plant cell a chimeric nucleic acid sequence molecule comprising in the 5' to 3' direction of transcription:

- 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
- 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
- 30 3) a third nucleic acid sequence capable of terminating transcription in said plant cell;

b) growing said plant cell into a mature plant capable of setting seed; and

c) obtaining said seed from said mature plant wherein the seed contains chymosin.

5 In a preferred embodiment, at least 0.5% (w/w) of the total seed protein is chymosin. More preferably at least 1% (w/w) of the total seed protein is chymosin, even more preferably at least 2% (w/w) of the total seed protein is chymosin and most preferably at least 4% (w/w) of the total seed protein is chymosin.

10 As used herein the term "chymosin polypeptide" refers to all chymosins and includes pre-pro-chymosin and pro-chymosin polypeptides. The chymosin is preferably mammalian such as bovine, goat and sheep chymosin.

The term "nucleic acid sequence encoding a chymosin
15 polypeptide" refers to all nucleic acid sequence encoding chymosin and all nucleic acid sequences that hybridize thereto under stringent hybridization conditions or would hybridize thereto but for the use of synonymous codons.

Appropriate "stringent hybridization conditions" which
20 promote DNA hybridization are known to those skilled in the art, or may be found in Current Protocols in Molecular Biology, John Wiley & Sons, N.Y. (1989), 6.3.1-6.3.6. For example, the following may be employed: 6.0 x sodium chloride/sodium citrate (SSC) at about 45°C, followed by a wash of 2.0 x SSC at 50°C. The stringency may be selected based on the conditions
25 used in the wash step. For example, the salt concentration in the wash step can be selected from a high stringency of about 0.2 x SSC at 50°C. In addition, the temperature in the wash step can be at high stringency conditions, at about 65°C.

The term "nucleic acid sequence encoding a chymosin
30 polypeptide" includes nucleic sequences that encode pre-pro-chymosin and pro-chymosin. In addition, the nucleic acid sequences that encode

chymosin may be linked to additional nucleic acid sequences such as those that encode signal peptides.

In preferred embodiments of the present invention, nucleic acid sequences encoding bovine chymosin A or chymosin B are used (Moir et al. (1982) Gene 19: 127-138.; Harris et al. (1982) Nucleic Acids Res. 10: 2177-2187). In further preferred embodiments nucleic acid sequences encoding chymosin are used which have been optimized for codon usage in plants. The natural bovine chymosin sequence has a GC content of 56% with a preference for a G or C in the third position of the codon. This differs from the codon bias for cattle which has an average GC content of 39% (Mishimori et al. (1982) J Biochem 91: 1085-1088). In a preferred embodiment, the codon usage of chymosin is manipulated to reflect a codon usage typical of seed-storage proteins found in oilseeds, for example using a GC content of 49% with a preference for a G or C in the third position of the codon (see Example 1).

The invention further includes the use of nucleic acid sequences encoding chymosin precursor proteins that can be activated, for example by treating the precursor polypeptide at low pH, to exhibit chymosin activity. Nucleic acid sequences encoding chymosin precursor proteins that may be used in accordance with the present invention include naturally occurring nucleic acid sequences encoding chymosin precursor proteins, such as "pro-chymosin", "pre-chymosin" and "pre-pro-chymosin", as well as non-naturally occurring nucleic acid sequences encoding precursor proteins comprising chymosin and capable of activation to exhibit chymosin activity. In a preferred embodiment of the invention, a nucleic acid sequence encoding bovine pro-chymosin comprising 42 extra amino acid residues is used (Moir et al. (1982) Gene 19: 127-138.; Harris et al. (1982) Nucleic Acids Res.10: 2177-2187). Other nucleic acid sequences encoding precursor proteins that may be used in accordance with the present invention include those encoding bovine pre-pro-chymosin comprising 58 extra amino acid residues (Moir et al. (1982) Gene 19: 127-138.; Harris et al. (1982) Nucleic Acids Res.10:

2177-2187), and nucleic acid sequences encoding plant signal sequences capable of targeting chymosin to a preferred subcellular compartment, for example the plant apoplast, the golgi apparatus or cytoplasm. In one preferred embodiment, the nucleic acid sequence encoding chymosin
5 comprises a nucleic acid sequence encoding the tobacco pathogenesis related protein-S (PR-S) signal sequence (Sijmons et al. (1990) Bio/technology 8: 217-221.) directing targeting to the plant apoplast linked to a nucleic acid sequence encoding a bovine pro-chymosin polypeptide sequence (Figure 1 and SEQ.ID.1). Other naturally occurring signal
10 sequences that could be used in accordance with the present invention include for example the barley alpha amylase signal sequence (Rogers (1985) J. Biol. Chem. 260(6): 3731-3738) directing targeting of the chymosin sequence to the apoplast. The nucleic acid sequences encoding additional peptide sequences may be homologous as well as heterologous with
15 respect to the nucleic acid sequence encoding the chymosin polypeptide. The nucleic acid sequence encoding the additional peptide sequences, such as the pro-peptide, pre-pro-peptide or pre-peptide, may vary in length and are preferably codon-optimized for use in plants.

In embodiments of the invention involving the activation of a
20 chymosin precursor protein, the activation reaction may be performed upon obtaining the plant seeds by for example treating an extracted seed fraction at low pH, preferably at pH values lower than 5, or the activation reaction may take place *in planta*. It is also possible to complete the activation reaction in a mixture comprising chymosin precursor
25 polypeptides and enzymatically active chymosin. The chymosin precursor protein may be partially active or exhibiting no chymosin activity, however the precursor protein is typically not fully active.

Nucleic acid sequences encoding chymosin are readily available or obtainable by the skilled artisan based on chymosin nucleic acid
30 sequences and/or amino acid sequences known in the art. The bovine nucleic acid and amino acid sequences for chymosin A and chymosin B for example, are known and may be directly used in accordance with the

present invention. As well, the complete primary structure of lamb preprochymosin has been deduced from cDNA (Pungercar et al. (1990) Nucleic Acids Res. 18(15): 4602). These known chymosin nucleic acid sequences may also be used to design and construct probes to identify
5 previously undiscovered nucleic acid sequences encoding chymosin. These probes may be used to isolate nucleic acid sequence encoding chymosin from for example cDNA or genomic libraries. The nucleic acid sequence encoding chymosin is preferably obtained from a mammal. Thus additional nucleic acid sequence chymosin sequences may be
10 discovered and used in accordance with the present invention.

The term "nucleic acid sequence" as used herein refers to a sequence of nucleotide or nucleoside monomers consisting of naturally occurring bases, sugars and intersugar (backbone) linkages. The term also includes modified or substituted sequences comprising non-naturally
15 occurring monomers or portions thereof, which function similarly. The nucleic acid sequences of the present invention may be ribonucleic (RNA) or deoxyribonucleic acids (DNA) and may contain naturally occurring bases including adenine, guanine, cytosine, thymidine and uracil. The sequences may also contain modified bases such as xanthine,
20 hypoxanthine, 2-aminoadenine, 6-methyl, 2-propyl, and other alkyl adenines, 5-halo uracil, 5-halo cytosine, 6-aza uracil, 6-aza cytosine and 6-aza thymine, pseudo uracil, 4-thiouracil, 8-halo adenine, 8-amino adenine, 8-thiol adenine, 8-thio-alkyl adenines, 8-hydroxyl adenine and other 8-substituted adenines, 8-halo guanines, 8-amino guanine, 8-thiol
25 guanine, 8-thioalkyl guanines, 8-hydroxyl guanine and other 8-substituted guanines, other aza and deaza uracils, thymidines, cytosines, adenines, or guanines, 5-trifluoromethyl uracil and 5-trifluoro cytosine.

In accordance with the present invention, the chimeric nucleic acid sequences can be incorporated in a known manner in a recombinant
30 expression vector which ensures good expression in a plant seed. Accordingly, the present invention includes a recombinant expression

vector comprising a chimeric nucleic acid sequence of the present invention suitable for expression in a seed cell.

5 The term "suitable for expression in a seed cell" means that the recombinant expression vectors contain the chimeric nucleic acids sequence of the invention, a regulatory region and a termination region, selected on the basis of the seed cell to be used for expression, which is operatively linked to the nucleic acid sequence encoding the polypeptide of desirable amino acid composition. Operatively linked is intended to mean that the chimeric nucleic acid sequence encoding the polypeptide is linked
10 to a regulatory sequence and termination region which allows expression in the seed cell. A typical construct consists, in the 5' to 3' direction of a regulatory region complete with a promoter capable of directing expression in a plant, a chymosin coding region and a transcription termination region functional in plant cells. These constructs may be prepared in
15 accordance with methodology well known to those of skill in the art of molecular biology (see for example: Sambrook et al. (1990) Molecular Cloning, 2nd ed. Cold Spring Harbor Press). The preparation of constructs may involve techniques such as restriction digestion, ligation, gel electrophoresis, DNA sequencing and PCR. A wide variety of cloning
20 vectors are available to perform the necessary cloning steps. Especially suitable for this purpose are the cloning vectors with a replication system that is functional in *Escherichia coli* such as pBR322, the pUC series M13mp series, pACYC184, pBluescript etc. The nucleic acid sequence may be introduced into these vectors and the vectors may be used to transform
25 *E. coli* which may be grown in an appropriate medium. Plasmids may be recovered from the cells upon harvesting and lysing the cells. Final constructs may be introduced into plant vectors compatible with integration into the plant such as the Ti and Ri plasmids.

30 The selection of regulatory sequences will determine the plant organ in which the protein is expressed and may influence the level that a gene will be transcribed. Regulatory sequences are art-recognized and are selected to direct expression in the plant cell. Accordingly, the term

"regulatory sequence" includes promoters, enhancers, ribosome binding sites, introns and other expression elements. Examples of promoters include both non-seed specific, constitutive promoters such as the 35-S CaMV promoter (Rothstein et al. (1987) Gene 53: 153-161) and seed specific
5 promoters such as the phaseolin promoter (Sengupta-Gopalan et al., (1985) PNAS USA 82: 3320-3324) or the *Arabidopsis* 18 kDa oleosin promoter (van Rooijen et al., (1992) Plant Mol. Biol. 18: 1177-1179). In preferred
embodiments of the present invention, seed specific promoters are employed and more specifically the phaseolin promoter. Enhancers which
10 may be used include the AMV leader (Jobling and Gehrke (1987) Nature 325: 622-625) to increase the expression levels. It should be understood that the design of the expression vector may depend on such factors as the choice of the plant species and/or the type of polypeptide to be expressed.

The region containing the transcriptional terminator sequence
15 preferably includes from about 200 to about 1,000 nucleotide base pairs and may comprise any such sequences functional in plants, such as the nopaline synthase termination region (Bevan et al., (1983) Nucl. Acid. Res. 11: 369-385), the phaseolin terminator (Van der Geest et al., (1994) Plant J. 6(3): 413-423), the terminator for the octopine synthase gene of
20 *Agrobacterium tumefaciens* or other similarly functioning elements. These transcription terminator regions can be obtained as described by An (1987) Methods in Enzym. 153: 292 or are already present in plasmids available from commercial sources such as ClonTech, Palo Alto, California. The choice of the appropriate terminator may have an effect of
25 the rate of transcription. In preferred embodiments of the invention the phaseolin terminator is employed.

The expression vectors may also contain a marker gene. Marker genes comprise all genes that enable distinction of transformed plant cells from non-transformed cells, including selectable and screenable
30 marker genes. Conveniently, a marker may be a resistance marker to a herbicide, for example, glyphosate or phosphinothricin, or to an antibiotic such as kanamycin, G418, bleomycin, hygromycin, chloramphenicol and

the like, which confer a trait that can be selected for by chemical means. Resistance markers to a herbicide when linked in close proximity to the chymosin gene may be used to maintain selection pressure on a population of transgenic plants for those plants that have not lost the gene
5 of interest. Screenable markers may be employed to identify transformants through observation. They include but are not limited to the beta-glucuronidase or *uidA* gene, a beta-lactamase gene or a green fluorescent protein (Niedz et al. (1995) Plant Cell Rep. 14: 403).

A variety of techniques are available for the introduction of
10 nucleic acid sequences, in particular DNA, into plant host cells. For example, the chimeric DNA constructs may be introduced into host cells obtained from dicotyledonous plants, such as tobacco, and oleagenous species, such as Brassica napus using standard *Agrobacterium* vectors by a transformation protocol such as described by Moloney et al. (1989) Plant
15 Cell Rep. 8: 238-242 or Hinchey et al. (1988) Bio/Technol. 6: 915-922; or other techniques known to those skilled in the art. For example, the use of T-DNA for transformation of plant cells has received extensive study and is amply described in EP 0 120 516, Hoekema et al., (1985), Chapter V In: The Binary Plant Vector System Offset-drukkerij Kanters BV,
20 Alblasterdam); Knauf et al. (1983), Genetic Analysis of Host Expression by *Agrobacterium*, p. 245, In: Molecular Genetics of Bacteria-Plant Interaction, Puhler, A. ed. Springer-Verlag, NY); and An et al., (1985) EMBO J., 4: 277-284. *Agrobacterium* transformation may also be used to transform monocot plant species (US Patent 5,591,616).

25 Conveniently, explants may be cultivated with *Agrobacterium tumefaciens* or *Agrobacterium rhizogenes* to allow for the transfer of the transcription construct in the plant host cell. Following transformation using *Agrobacterium* the plant cells are dispersed into an appropriate medium for selection, subsequently callus, shoots and eventually plants
30 are recovered. The *Agrobacterium* host will harbour a plasmid comprising the *vir* genes necessary for transfer of the T-DNA to plant cells. For injection and electroporation (see below) disarmed Ti-plasmids

(lacking the tumour genes, particularly the T-DNA region) may be introduced into the plant cell.

The use of non-*Agrobacterium* techniques permits the use of constructs described herein to obtain transformation and expression in a wide variety of monocotyledenous and dicotelydenous plant species. These techniques are especially useful for transformation of plant species that are intractable in an *Agrobacterium* transformation system. Other techniques for gene transfer include particle bombardment (Sanford, (1988) Trends in Biotechn. 6: 299-302), electroporation (Fromm et al., (1985) PNAS USA, 82: 5824-5828; Riggs and Bates, (1986) PNAS USA 83: 5602-5606), PEG mediated DNA uptake (Potrykus et al., (1985) Mol. Gen. Genetics., 199: 169-177), microinjection (Reich et al., Bio/Techn. (1986) 4:1001-1004) and silicone carbide whiskers (Kaeppler et al. (1990) Plant Cell Rep. 9: 415-418).

In a specific application such as to *B. napus*, the host cells targeted to receive recombinant DNA constructs typically will be derived from cotyledonary petioles as described by Moloney et al. (1989) Plant Cell Rep. 8: 238-242. Other examples using commercial oil seeds include cotyledon transformation in soybean explants (Hinchee et al., (1988) Bio/Technol. 6: 915-922 and stem transformation of cotton (Umbeck et al., (1987) Bio/Technol. 5: 263-266).

Following transformation, the cells, for example as leaf discs, are grown in selective medium. Once the shoots begin to emerge, they are excised and placed onto rooting medium. After sufficient roots have formed, the plants are transferred to soil. Putative transformed plants are then tested for presence of a marker. Southern blotting may be performed on genomic DNA using an appropriate probe, to show integration into the genome of the host cell.

Transformed plants grown in accordance with conventional agricultural practices, are allowed to set seed. See, for example, McCormick et al. (1986) Plant Cell Reports 5: 81-84. The chymosin expression level that is attained in accordance with the present invention, is generally expected to vary somewhat depending on the transformed plant that is assayed. As

hereinbefore mentioned for the process to be economically attractive, a minimum expression level is required. The terms "commercial" and "commercial levels" as used herein denote an expression level wherein at least 0.5% (w/w) and more preferably more than 2% (w/w) and most preferably more than 4% (w/w) of total seed protein is chymosin. Preferably expression levels are determined using quantitative Western blotting using the methodology described in detail in Example 2. Accordingly, typically a variety of transformed plants are screened and the expression level of chymosin in seed is determined. It is expected that typically between 5 and 50 plants may need to be screened to identify at least one plant expressing commercial levels of chymosin. Seeds obtained from plants expressing commercial levels of chymosin (i.e. at least 0.5% (w/w) of the total seed protein) are selected for further propagation.

Accordingly, the present invention provides a method for the production of plant seeds containing at least 0.5% ((w/w) chymosin in the total seed protein comprising:

- (a) introducing into each of at least two plant cells a chimeric nucleic acid sequence molecule comprising in the 5' to 3' direction of transcription:
 - 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
 - 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
 - 3) a third nucleic acid sequence capable of terminating transcription in said plant cell;
- (b) growing each plant cell into a mature plant capable of setting seed;
- (c) obtaining seed from each mature plant;
- (d) detecting the levels of chymosin in the seed of each plant obtained in step (c) or in the seed of a plant generated from the seed of a plant obtained in step (c); and

(e) selecting plants that contain at least 0.5% (w/w) chymosin in the total seed protein.

Chymosin activity can be assayed by spectrophotometric or fluorometric methods or by milk-clotting assays. In the milk-clotting assay, a diluted sample is added to a milk solution so that the final solution contains 8% skim milk and 0.05% CaCl_2 in water. The clotting time or flake point is measured as the time it takes for the thin film of milk to break into visible particles. The concentration of chymosin is determined by comparing to a linear standard plotted as clotting time in seconds against the chymosin concentration (Tsuchiya et al. (1993) Appl. Microbiol. Biotechnol. 40: 327-332).

Two or more generations of plants may be grown and either crossed or selfed to allow identification of plants and strains with desired phenotypic characteristics including production of the recombinant polypeptide. It may be desirable to ensure homozygosity in the plants to assure continued inheritance of the recombinant trait. Methods for selecting homozygous plants are well known to those skilled in the art of plant breeding and include recurrent selfing and selection and anther and microspore culture. Homozygous plants may also be obtained by transformation of haploid cells or tissues followed by regeneration of haploid plantlets subsequently converted to diploid plants by any number of known means (e.g. treatment with colchicine or other microtubule disrupting agents).

The present invention also provides plant seeds expressing chymosin. In a preferred embodiment of the present invention the plant seeds comprise a chimeric nucleic acid sequence comprising in the 5' to 3' direction of transcription:

- 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
- 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;

- 3) a third nucleic acid sequence capable of terminating transcription in said plant cell, wherein the seed contains chymosin.

In a further aspect the present invention provides plants capable of setting seed expressing chymosin. In a preferred embodiment of the invention, the plants capable of setting seed comprise a chimeric nucleic acid sequence comprising in the 5' to 3' direction of transcription:

- 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
- 10 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
- 3) a third nucleic acid sequence capable of terminating transcription in said plant cell, wherein the seed contains chymosin.

15 The methods disclosed in the present invention can be used over a broad range of plant species. Particularly preferred plant cells employed in accordance with the present invention include cells from the following plants: soybean (*Glycine max*), rapeseed (*Brassica napus*, *Brassica campestris*), sunflower (*Helianthus annuus*), cotton (*Gossypium*
20 *hirsutum*), corn (*Zea mays*), tobacco (*Nicotiana tabacum*), alfalfa (*Medicago sativa*), wheat (*Triticum sp.*), barley (*Hordeum vulgare*), oats (*Avena sativa* L.), sorghum (*Sorghum bicolor*), Arabidopsis thaliana, potato (*Solanum sp.*), flax/linseed (*Linum usitatissimum*), safflower (*Carthamus tinctorius*), oil palm (*Eleais guineensis*), groundnut (*Arachis*
25 *hypogaea*), Brazil nut (*Bertholletia excelsa*) coconut (*Cocus nucifera*), castor (*Ricinus communis*), coriander (*Coriandrum sativum*), squash (*Cucurbita maxima*), jojoba (*Simmondsia chinensis*) and rice (*Oryza sativa*).

The invention also provides a method for recovering chymosin from a plant seed comprising:

- 30 a) introducing into a plant cell a chimeric nucleic acid sequence molecule comprising in the 5' to 3' direction of transcription:

new
in CIP

- 1) a first nucleic acid sequence capable of regulating transcription in said plant cell operatively linked to;
 - 2) a second nucleic acid sequence encoding a chymosin polypeptide operatively linked to;
 - 5 3) a third nucleic acid sequence capable of terminating transcription in said plant cell;
- b) growing said plant cell into a mature plant capable of setting seed;
- c) obtaining seed from the mature plant wherein said seed
- 10 contains chymosin; and
- d) isolating said chymosin from said seed.

In preferred embodiments, isolation of chymosin from seed comprises:

- i) crushing the plant seed to obtain crushed plant seed;
- 15 ii) contacting the crushed plant seed or a fraction thereof with a protein binding resin; and
- iii) recovering chymosin from the protein binding resin.

The term "crushing" as used herein refers to any process or methodology to comminute seed and includes mechanical pressing, grinding, crushing processes and the like. Preferably the seeds are ground using a mill such as for example a colloid mill, a disk mill, a pin mill, an orbital mill, an IKA mill, a homogenizer or similar equipment. The selection of the crushing equipment depends inter alia on the throughput requirements and on the seed source. Typically the crushing conditions

20 selected result in the breakage of individual seed cells. It is of importance however that the chymosin polypeptide remains intact. Crushing conditions that would substantially inactivate the enzyme are undesirable in the practice of the present invention. The crushing process practiced in accordance with the present invention permits the recovery of a crushed

25 plants seeds comprising chymosin.

The crushing process may be carried out using dry seed. Preferably however the seeds are crushed in the presence of water or a

buffer. Prior to, during or after the crushing process, additional water or a buffer may be employed to dilute the seed extract. Preferably the crushed seed fraction obtained is between 2 and 100 fold diluted relative to the original seed volume. Furthermore the salt concentration may be
5 adjusted by the addition of extraneous salts or salt solutions to the crushed seeds. Accordingly, preferably the extraneous salt concentration of the crushed seed that is obtained is preferably between approximately 0.1M and 2M. Suitable salts to adjust the salt concentration in accordance with the present invention include sulfate salts for example sodium sulfate,
10 magnesium sulfate, and ammonium sulfate; phosphate salts, for example sodium phosphate, magnesium phosphate and ammonium phosphate; chloride salts, for example sodium chloride and calcium chloride; and mixtures thereof. A preferred salt used in accordance with the present invention is sodium chloride.

15 Upon crushing of the seed it is generally preferable to prepare an aqueous fraction of the crushed plant seeds by the removal of the insoluble material and the oil fraction of the seed. The insoluble material is substantially insoluble or in an insolublized association with insoluble material produced upon crushing of the plant seed material. The
20 insoluble material is either produced in the plant seed or may be associated with the plant seed in the form of insoluble aggregates including, seed hulls, fibrous material, carbohydrates or external contaminants such as soil particles and the like. The process permits the separation of soluble seed material from insoluble seed material. Any suitable methodology may use
25 be accomplished using any methodology that allows the separation of the seed insoluble material from the soluble seed constituents, including for example gravitation based methods such as for example centrifugation or size exclusion based methods such as filtration. In a preferred embodiment of the present invention centrifugation is used.
30 Centrifugation equipment that may be used in accordance with the present invention includes a tubular bowl centrifuge, a decantation centrifuge, a hydrocyclone, a disk stack centrifuge, and the like.

Removal of the oil fraction is particularly desirable when chymosin is produced in seeds comprising a relatively high oil content such as rapeseed, flax, sunflower seed and the like. Any suitable methodology may be used that allows the separation of the oil fraction
5 from the aqueous fraction of the seed, including for example gravitation based methods such as for example centrifugation or size exclusion based methods such as filtration. In a preferred embodiment of the present invention centrifugation is used. Centrifugation equipment that may be used in accordance with the present invention includes a tubular bowl
10 centrifuge, a decantation centrifuge, a hydrocyclone, a disk stack centrifuge, and the like.

Generally the solids are removed prior to the oil fraction, however in other embodiments of the invention the removal of insoluble seed constituents and the oil fraction is accomplished concomitantly using
15 a gravity based method such as a 3-phase tubular bowl centrifuge or decanter or a size-exclusion based separation method.

In a further preferred embodiment selective precipitation of the crushed plant seed extract or fraction thereof may be performed prior to contacting the plant seed extract or fraction thereof with the protein
20 binding resin. This selective precipitation step is preferably accomplished by selecting any conditions that allow the precipitation of at least 50% (w/w) of the endogenous seed proteins while substantially all chymosin remains soluble. With the term "substantially all" it is meant that at least approximately 75% (w/w) of all chymosin remains soluble. In a more
25 preferred embodiment at least 85% (w/w) of all chymosin remains soluble. In the most preferred embodiment at least approximately 90% (w/w) of all chymosin remains soluble. In preferred embodiments of the present invention precipitation is accomplished by adjusting the pH of the crushed seed extract. The pH of the crushed seed is preferably adjusted to a pH of
30 less than approximately 5.5. More preferably the pH is adjusted to a pH of between approximately 1.5 and 3.5. Most preferably the pH is adjusted to a pH of approximately 2.0. Any suitable acid may be used to adjust the pH,

such as hydrochloric acid, sulfuric acid, phosphoric acid and the like preferably having a pH of less than 2. The precipitation step may take place concomitantly with the crushing step. In preferred embodiments, the precipitation step is performed subsequent to the seed-crushing step.

- 5 Furthermore the precipitation may be performed prior to or subsequent to either the removal of the insoluble material or removal of the oil fraction. It is preferred however to remove the insoluble material and the oil fraction prior to selective precipitation.

10 The term "protein binding resin" means any resin that is capable of binding to proteins, in particular chymosin. In a preferred embodiment, the protein binding resin is a hydrophobic interaction resin.

The present inventors have found that a hydrophobic interaction resin is particularly useful in isolating chymosin from plant seeds. A "hydrophobic interaction resin" refers to any protein compatible
15 resin capable of differentially binding proteins present in a mixture of proteins, said differential binding occurring as a result of differences in hydrophobic characteristics of the proteins present in the mixture. Hydrophobic interaction resins are generally art-recognized and include for example sepharose resins having functional groups such as alkyl
20 groups (e.g. butyl-sepharose, octyl-sepharose) and phenyl groups (e.g. phenyl-sepharose) and superose resins having functional groups such as alkyl groups and phenyl groups. The hydrophobic interaction resin may be used batch-wise or prepared for column chromatography.

In the practice of the present invention the crushed seed extract
25 or a fraction thereof comprising chymosin is contacted with the hydrophobic interaction resin under conditions that will permit chymosin to bind to the hydrophobic interaction resin. Preferred binding conditions in accordance with the present invention are conditions of high ionic strength, for example 1M to 2M salt concentrations, e.g. 1.5M ammonium
30 sulphate. Other salts that may be used in accordance with the present invention include sulfate salts for example magnesium sulfate; phosphate salts, for example sodium phosphate, magnesium phosphate and

ammonium phosphate; chloride salts, for example sodium chloride and calcium chloride; and mixtures thereof. Once binding has been accomplished conditions are altered so that the bound substances are eluted differentially thus allowing the recovery of chymosin from the hydrophobic interaction column. Preferably the ionic strength is altered to accomplish elution, for example the ionic strength is reduced from 1.5 M to 0.5 M. The changes in conditions may be performed stepwise or gradually. Other elution methodologies that may be employed include reducing the eluent polarity for example using a glycol gradient up to 50%, adding chaotropic species such as urea, guanidine hydrochloride; the addition of detergents; changing pH or temperature.

In further preferred embodiments, chymosin is additionally purified by employing an ion exchange resin. An "ion exchange resin" refers to any protein compatible resinous material which is capable of binding charged compounds. Ion exchange columns are art recognized and include anion and cation exchange resins. These resins may be employed in a batch fashion or as a column. Preferred cation exchange columns for use in the present invention, include for example Pharmacia SP-Sephadex, Indion SP-2, IBF SP-Triacryl, IBF SP-Spherodex and the like. Preferred anion exchange resins in this regard are DEAE cellulose, IBF Q Spherodex, Pharmacia Q-Sephadex, Indion Q-2, IBF Q-Trisacryl and the like. In the practice of the present invention the aqueous solution of comprising chymosin is contacted with the ion-exchange resin under conditions at which the chymosin will bind to the resin. Whether chymosin binds to the resin depends on the pH of the aqueous solution, i.e. whether the pH is below or above the isoelectric point of chymosin (approximately 4.6). Accordingly, contacting the aqueous solution comprising chymosin under conditions at which chymosin will bind to the column refers to adjusting the pH of the solution above or below its isoelectric point so that it will bind to the selected resin. Binding of chymosin to the resin further depends on the ionic strength. Accordingly, the salt concentration may vary, for example a concentration of less than

250mM NaCl may be used. In order to elute chymosin of the resin conditions are selected which permit the elution of chymosin from the resin, preferably the ion concentration is adjusted to elute the chymosin of the resin. For example the salt concentration may be adjusted to a concentration of 2M NaCl. The pH and salt concentration of the chymosin preparation thus recovered may be adjusted as desired. The ion exchange resin step may be employed either prior or after the hydrophobic interaction step.

Optionally the chymosin preparation may be concentrated using for example ultrafiltration or treated for longer-term preservation using any suitable preservation methodology. For example the chymosin preparation may be sterilized using methodologies such as filtration or ultrafiltration.

Optionally the chymosin preparation may be concentrated using for example ultrafiltration or treated for longer-term preservation using any suitable preservation methodology. For example the chymosin preparation may be sterilized using methodologies such as filtration or ultrafiltration.

The following non-limiting examples are illustrative of the present invention:

EXAMPLES

EXAMPLE 1

Construction of a plant transformation vector comprising of a chimeric nucleic acid sequence containing *pre-pro-chymosin*.

A pro-chymosin gene was re-synthesized from the bovine pro-chymosin to reflect the plant-preferred codons (See Figure 1 and SEQ.ID.NOS.: 1 and 2). Amino acids 27 to 67 are the pro-peptide sequence and amino acids 68 to 390 are the mature chymosin polypeptide. A PR-S signal sequence was attached to the 5' end of the pro-chymosin gene by PCR fusion. The PRS sequence includes amino acids 1 to 26 in Figure 1. The pre-pro-chymosin DNA fragment was fused in between a phaseolin promoter and the phaseolin terminator derived from the common bean

Phaseolus vulgaris Slightom et al (1983) Proc. Natl Acad Sc USA 80: 1897-1901). A complete sequence of the phaseolin promoter-preprochymosin-phaseolin terminator insert responsible for the expression of chymosin in plant seeds is shown in Figure 2 and
5 SEQ.ID.NO.:3. This insert was cloned into the PstI-KpnI sites of vector pSBS2004 and pSBS3000 and resulted in plasmids pSBS2151 and pSBS2165 respectively. pSBS2004 is a derivative from the *Agrobacterium* binary plasmid pCGN1559 (MacBride and Summerfield, 1990, Plant Molec. Biol. 14 269-276) in which, the CAMV 35S promoter-neomycin
10 phosphotransferase gene- tumor morphology large locus 3' antibiotic selection cassette of pCGN1559 was replaced with parsley ubiquitin promoter-phosphinothricin acyltransferase gene-parsley ubiquitin termination sequence to confer resistance to the herbicide glufosinate ammonium. pSBS3000 is a derivative from the *Agrobacterium* binary
15 plasmid pPZP221 (Hajdukiewicz et al., 1994, Plant Molec. Biol. 25: 989-994). In pSBS3000, the CaMV35S promoter-gentamycin resistance gene-CAMV 35S terminator of pPZP221 was replaced with parsley ubiquitin promoter-phosphinothricin acetyl transferase gene-parsley ubiquitin termination sequence to confer resistance to the herbicide glufosinate
20 ammonium.

EXAMPLE 2

Generation of chymosin-expressing transgenic plants

Plasmids pSBS2151 and pSBS2165 were electroporated into *Agrobacterium* strain EHA101 (Hood, et al (1986) J Bacteriol 144: 732-743).
25 *Agrobacterium* strain EHA101 (pSBS2151) was used to transform *Brassica napus*. The procedure for the transformation of *Brassica* has been essentially outlined in Moloney et al. (1989) Plant Cell Reports 8: 238-242, except phosphinothricin, at a concentration of 1 to 2 mg/L, was used as the selectable agent. *Agrobacterium* strain EHA101 (pSBS2165) was used to
30 transform flax cv Mc Gregor. Flax transformation was performed essentially as described in Jordan and McHughen (1988) Plant cell reports 7:

281-284, except transgenic shoots were selected on 10 μ M L-phosphinothricine instead of kanamycin.

EXAMPLE 3

Expression levels of chymosin in *Brassica*

5 Physical characteristics of *Brassica napus* seed extracted
chymosin were compared relative to commercially available bovine
chymosin. The molecular weight of the two chymosin proteins was
determined by gel electrophoresis on a 12% poly-acrylamide gel and
Western blot analysis using a polyclonal rabbit antibody as shown in
10 Figure 3. Specified concentrations were loaded onto a 12% poly-acrylamide
gel and transferred to a membrane. The membrane was probed with a
polyclonal antibody raised against commercial available bovine chymosin
and visualized using alkaline phosphatase. This polyclonal antibody is
immunologically reactive with several bands in the transgenic seed
15 extract. Bands of the same electroforetic mobility are found in the
commercial bovine chymosin extract. This suggests that the majority of
the pre-pro-chymosin in the seed extract has matured into chymosin. The
lower molecular weight bands likely result from proteolytic digestion of
the mature protein and the minor higher molecular weight bands could
20 correspond to altered processed forms of either preprochymosin or
prochymosin. The protein levels for chymosin in one of the *Brassica*
plants analyzed is shown in Figure 3. Seeds were ground in water to make
a seed extract and the protein concentration was determined as described
in Bradford (1976) Anal. Biochem. 72: 248-254. Different concentrations of
25 the same seed extract were electrophoresed on a gel along with a bovine
derived chymosin standard loaded with known concentrations. Western
blot analysis was performed with a polyclonal rabbit antibody and
visualized using alkaline phosphatase. Quantitative densitometry was
used to correlate the density of the 35.6 kDa band to the concentration of
30 the protein by comparison with a standard curve derived from known
concentrations of chymosin. Table 1 is a compilation of the data for the
amount of chymosin in the identical seed extract of differing

concentrations and resulting percent of expression. The slightly different levels reflect a standard error. Note that no data is provided for 4 µg and 8 µg of seed extract as the results exceeded the saturation range of the densitometer.

- 5 The biological activity of the plant (Brassica) derived chymosin was determined through the use of milk-clotting assays. In the milk-clotting assay, a diluted seed extract sample is added to a clotting substrate as described in (Tsuchiya et al. (1993) Appl. Microbiol. Biotechnol. 40: 327-332). Transgenic Brassica seeds had the ability to clot
- 10 milk whereas, seeds that were not transformed with the pro-chymosin gene were unable to clot milk.

EXAMPLE 4

Expression levels of chymosin in flax (*Linum usitatissimum*)

- 15 Transgenic flax plants containing the preprochymosin gene were analyzed for the presence of biologically active chymosin. The biological activity of the plant derived chymosin was determined through the use of milk-clotting assays. In the milk-clotting assay, a diluted flax seed extract sample is added to a clotting substrate as described in (Tsuchiya et al. (1993) Appl. Microbiol. Biotechnol. 40: 327-332). The
- 20 clotting time or flake point is measured as the time it takes for the thin film of milk to break into visible particles. The concentration of chymosin in the seed extract is determined by comparing it to a linear standard curve plotted as clotting time in seconds against the chymosin concentration (Tsuchiya et al. (1993) Appl. Microbiol. Biotechnol. 40: 327-332). The
- 25 chymosin concentration was first determined as a weight percentage of seed weight (=W%). The percentage chymosin as a percentage of total seed protein was calculated by using the formula (W/ percentage protein in dry seed) X 100. For flax the total amount of protein as a percentage of seed weight equals approximately 20 % (Gill, 1987, Linseed, Indian Council of
- 30 Agricultural Research Publication). Wx5 equals the expression level of chymosin as a percentage of total seed protein. Figure 4 shows the

expression levels of chymosin in transgenic flax seeds as a percentage of total protein for selected transformants.

EXAMPLE 5

Purification of chymosin from transgenic *Brassica napus* seed

5 This example describes the laboratory-scale purification of
chymosin from transgenic seed produced as described in example 2. Forty
grams of transgenic *Brassica napus* seed containing recombinant chymosin
was combined with 400 mls of a solution containing 250 mM NaCl. The
mixture was ground using a polytron to produce a slurry releasing the
10 chymosin into solution. This slurry was then centrifuged at
approximately 10,000 x g to separate it into three phases, a solid pellet,
phase of insoluble material, an upper phase of seed oil bodies and
associated proteins and a middle aqueous phase containing the chymosin,
soluble seed proteins and other soluble seed components. Following
15 centrifugation, the aqueous phase was removed and clarified by filtration.
The clarified extract was adjusted to a pH of 2.0 by addition of sulfuric acid
and allowed to sit for several minutes and then readjusted to pH 5.6 with
aqueous ammonia. The extract was then centrifuged at 10,000 x g to
remove precipitated proteins and the soluble supernatant phase recovered.
20 The low pH-treated extract was diluted with water to a conductivity of
approximately 9.5 mmohs and then loaded on to an anion exchange
column containing approximately 30 mls of DEAE-cellulose previously
equilibrated with 0.5% sodium benzoate, 0.379% NaCl, pH 5.6. After
loading, the column was washed with approximately 200 mls of 0.5%
25 sodium benzoate, 0.379% NaCl, pH 5.6 and then eluted with 110 mls of
0.5% sodium benzoate, 10% NaCl, pH 5.6. The eluate from the anion
exchange step was loaded on to a gel filtration column containing G25
sephadex (Amersham-Pharmacia) equilibrated with 25 mM sodium
phosphate, 1 M ammonium sulfate, pH 5.6. Fifty mls of the eluate from
30 this column was passed through a 0.22 um filter and then loaded on to a
hydrophobic interaction column containing 4.6 mls of butyl sepharose
(Fast Flow, Amersham-Pharmacia) previously equilibrated with 25 mM

sodium phosphate, 1 M ammonium sulfate, pH 5.6. After loading, the column was washed with 20 mls of 25 mM sodium phosphate, 1 M ammonium sulfate, pH 5.6 followed by 75 mls of 25 mM sodium phosphate, 0.55 M ammonium sulfate, pH 5.6. Purified chymosin was
5 eluted from the column with 24 mls of 25 mM sodium phosphate, 0.1 M ammonium sulfate, pH 5.6. Figure 5 shows a SDS-polyacrylamide gel showing progressive purification of chymosin obtained from transgenic seeds of Brassica napus as described above. Lane 1, aqueous phase from total seed extract; lane 2 pH-treated extract; lane 3, DEAE-cellulose eluate;
10 lane 4, purified chymosin eluted from butyl sepharose.

While the present invention has been described with reference to what are presently considered to be the preferred examples, it is to be understood that the invention is not limited to the disclosed examples. To the contrary, the invention is intended to cover various modifications and
15 equivalent arrangements included within the spirit and scope of the appended claims.

All publications, patents and patent applications are herein incorporated by reference in their entirety to the same extent as if each individual publication, patent or patent application was specifically and
20 individually indicated to be incorporated by reference in its entirety.

TABLE 1

| | | | |
|---|-----|------|-----|
| mg of seed extract | 0.5 | 1.0 | 2.0 |
| ng of pro-chymosin in seed extract | 21 | 47 | 88 |
| level of expression (% of protein) | 4.2 | 4.7 | 4.4 |
| Average level of expression (% of protein) | | 4.43 | |
